## Acknowledgments

The authors wish to express their gratitude to geologist D. Prior for reviewing an earlier version of the manuscript and pilots Howard Vigneault and Steve Wotton of Highland Helicopter Ltd. for their skilled and safe flying to landings near sampling sites. G. Hippolt-Squair is thanked for performing the final manuscript review.

## Abstract

In 2004, a National Geochemical Reconnaissance Survey (NGR) stream sediment and stream water geochemical survey was undertaken by the Geological Survey of Canada (GSC) and Alberta Geological Survey (AGS) in the northern and southern parts of the Buffalo Head Hills of north-central Alberta. Results from the 2004 survey augment NGR data obtained in the Buffalo Head Hills area during 2001, 2002 and 2003.

Preliminary analytical data, obtained from samples collected at 122 field sites in 2004, are released in this report for

- (a) stream sediment nickel, copper, zinc, arsenic, molybdenum, silver, barium, mercury and lead, and
- (b) stream water pH and conductivity.

The reader is cautioned that not all of the usual NGR quality control checks have been performed on the analytical data contained in this report. However, the results of the 2004 survey are believed to have mineral exploration and environmental significance, and an early release of information was deemed appropriate.

Markedly acidic waters occur in some streams draining the northern Buffalo Head Hills (pH values as low as 3.3). In addition, streams draining the northern and northeastern flanks of the Buffalo Head Hills are commonly characterized by relatively elevated conductivity values. In comparison to stream sediments from other parts of the Buffalo Head Hills area, the stream sediments (silts) collected from streams flanking the northern Buffalo Head Hills tend to contain elevated amounts of nickel, copper, zinc, molybdenum, silver, mercury, lead and, to a lesser extent, barium.

## **1 Introduction**

In 2004, a National Geochemical Reconnaissance Survey (NGR) stream sediment and stream water geochemical survey was undertaken by the Geological Survey of Canada (GSC) and Alberta Geological Survey (AGS) in the northern and southern parts of the Buffalo Head Hills of north-central Alberta (Figure 1). Results from the 2004 survey augment NGR data obtained in the Buffalo Head Hills area during 2001, 2002 and 2003 (Friske et al., 2003; McCurdy et al., 2004). The Buffalo Head Hills form a northerly trending upland region lying between the Peace River Lowland (Cadotte Plain) to the west and the Wabasca Lowland (Loon Lake Plain) to the east (Pettapiece, 1986). Access to sample sites was mainly by helicopter from La Crete for the northern survey area, and Red Earth Creek for the southern survey area.

Preliminary analytical data are released in this report for nickel, copper, zinc, arsenic, molybdenum, silver, barium, mercury and lead contents of stream sediment samples collected from 122 field sites in 2004 (Figure 2; Appendix 1; Appendix 2). Also released are stream water pH and conductivity measurements collected by field personnel. A considerable amount of additional analytical data obtained from the 2004 survey will be released later. The reader is cautioned that not all of the usual NGR quality control checks have been performed on the analytical data contained in this report. However, the results of the 2004 survey are believed to have mineral exploration and environmental significance, and an early release of some information was deemed appropriate.

This NGR project is aligned with Alberta's plan for a multi-year, multi-disciplinary geochemical and indicator mineral study in the northern part of the province. The Geological Survey of Canada, under the Targeted Geoscience Initiative II (TGI II) and Northern Resources Development Program, and the Alberta Energy and Utilities Board/Alberta Geological Survey (EUB/AGS) funded the 2004 survey. Analytical results and field observations contribute to building a national geochemical database for resource assessment, mineral exploration, geological mapping and environmental studies. Sample collection, preparation procedures and analytical methods are strictly specified and carefully monitored to ensure consistent and reliable results regardless of the area, the collection year or the analytical laboratory undertaking the analyses (Friske and Hornbrook, 1991).

## **2 Sample Collection**

### **2.1 Stream Sediment (Silt) Samples**

At each site, a pre-labelled Kraft paper bag (12.5 cm x 28 cm with side gussets) was two-thirds filled with silt and/or very fine-grained to fine-grained sand collected from the active stream channel. Although the samples commonly contain sand and may contain clay in addition to silt, these samples are traditionally referred to as silt samples. In practice, the stream silt sample was collected after water samples were collected, but before collection of a bulk sediment sample. Commonly, the sampler collected handfuls of fine-grained sediment from various points in the active stream channel while moving gradually upstream. If the stream channel consisted mainly of clay, coarse material or organic sediment from which suitable sample material is scarce or absent, moss mat from the stream channel, which commonly contains trapped silt, may have been added to the sample. Sample descriptions are provided in Appendix 3. Flagging tape with a sample site number was used to mark sample sites.

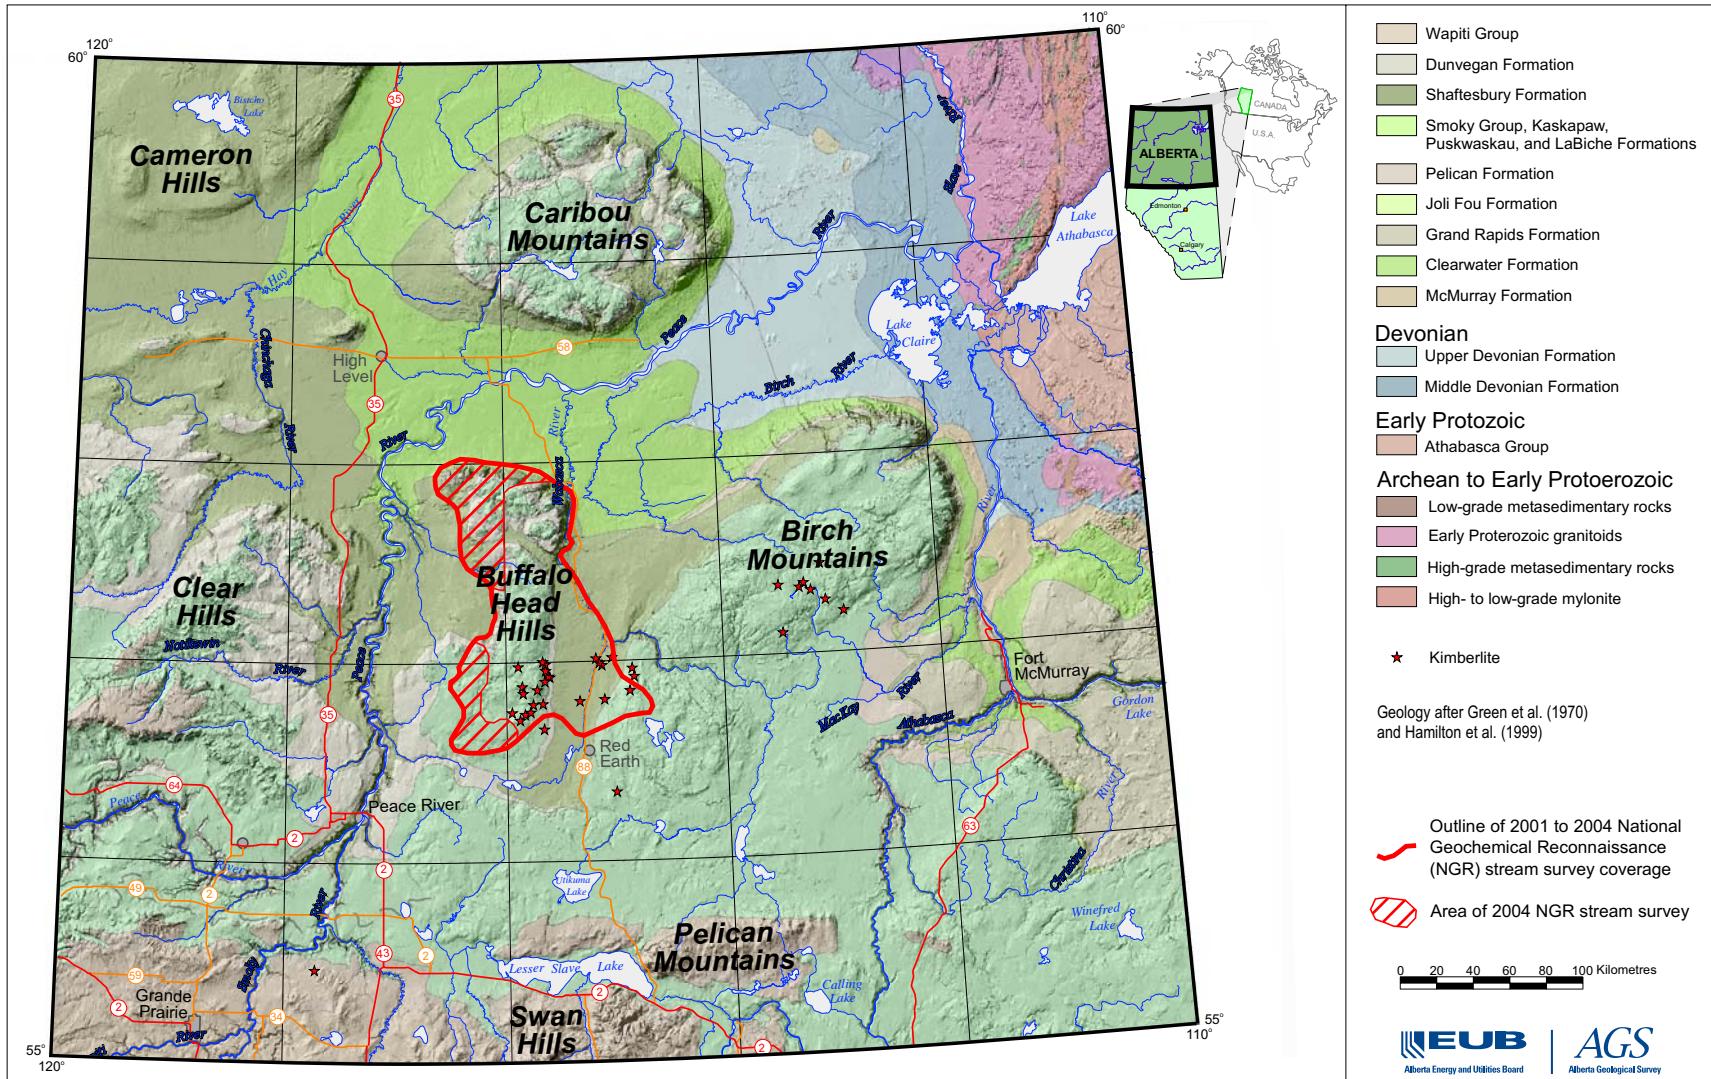

Figure 1. Location of 2004 stream survey.

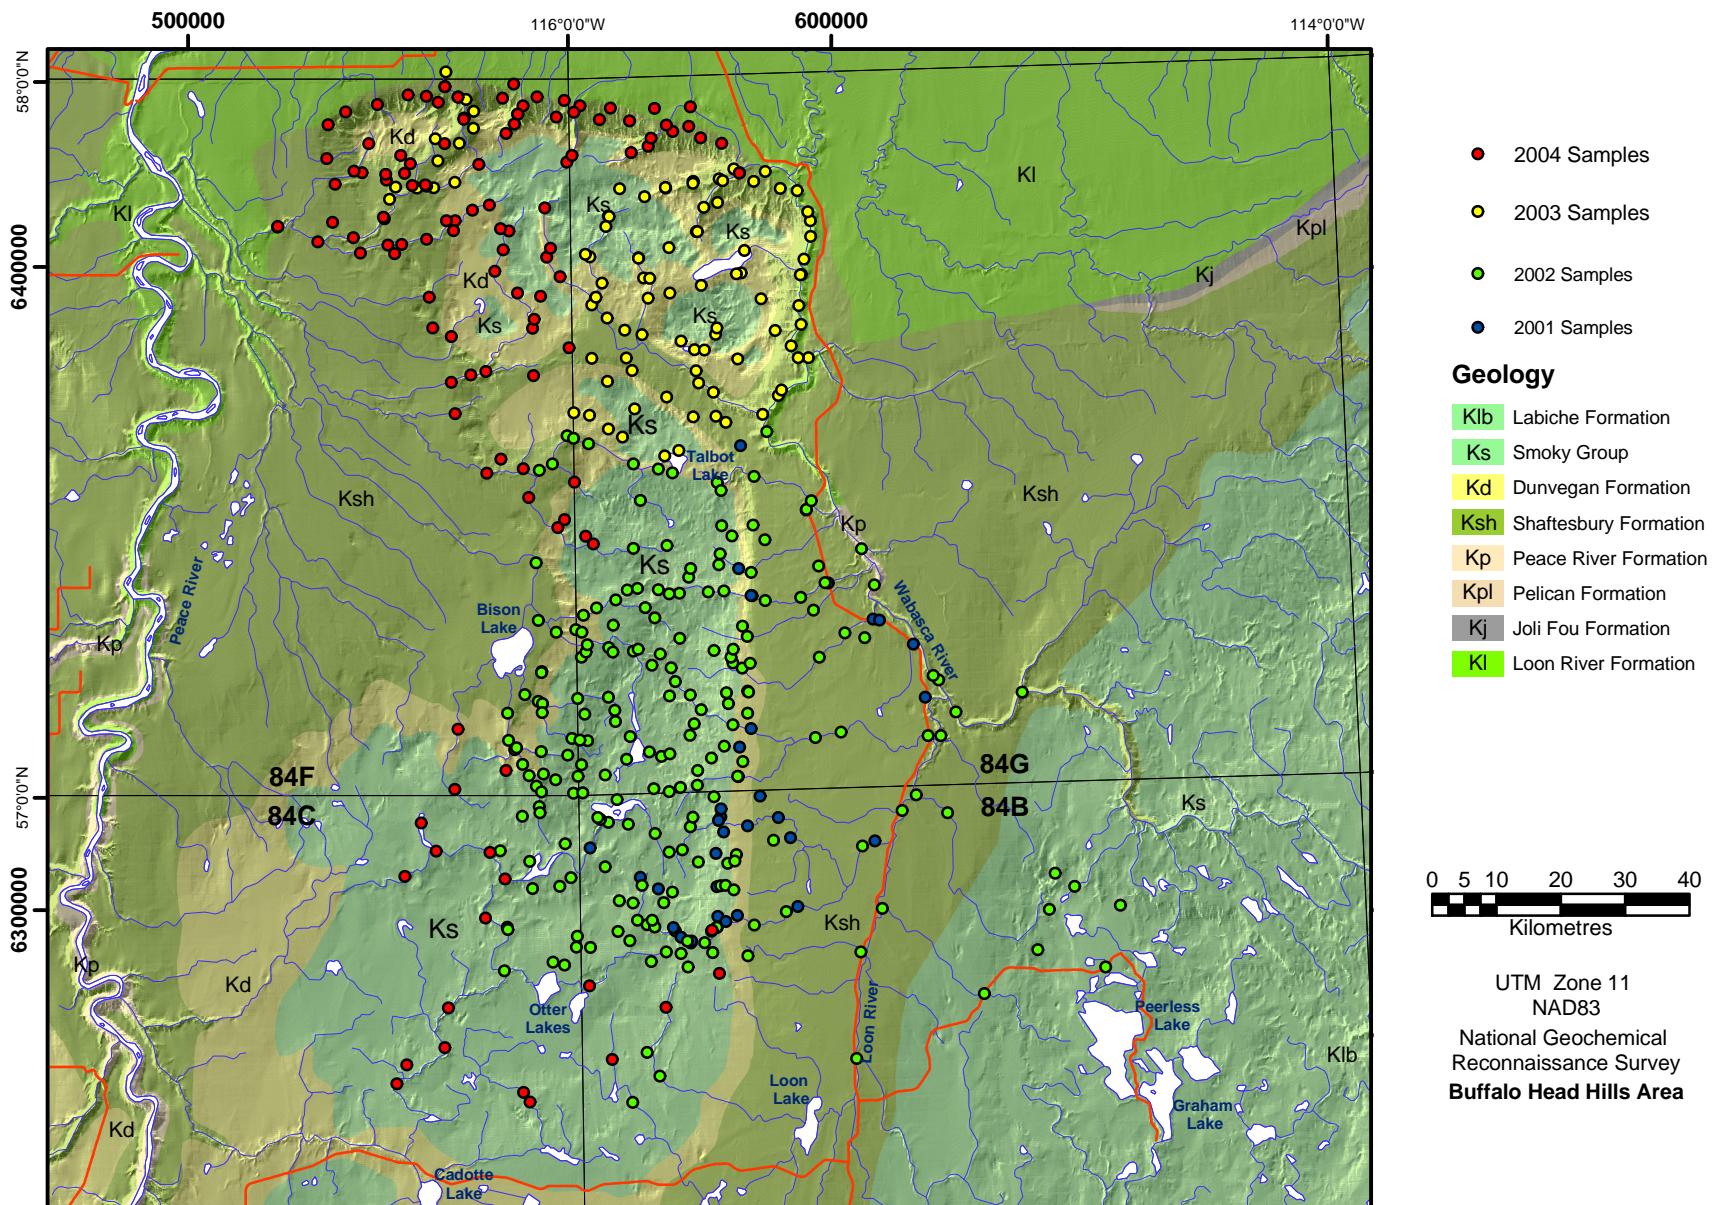

Figure 2. Distribution of 2001 to 2004 sample sites in the Buffalo Head Hills area.

## **2.2 Stream Waters**

Water samples were sampled in mid-channel, from flowing water where possible, at every site. Samples were collected in two 125-ml Nalgene high-density polyethylene (HDPE) bottles. Samples were collected after first rinsing each bottle three times in flowing water before a final fill. Sample descriptions are provided in Appendix 3.

## **3 Sample Preparation**

### **3.1 Stream Sediment (Silt) Samples**

The Kraft paper bags containing the stream silt samples were placed into plastic bags, taped with electrical tape and shipped directly to Acme Analytical Laboratories of Vancouver, British Columbia, where they were air-dried at temperatures below 40°C and sieved through a minus 80-mesh (177 µm) screen. Control reference and blind duplicate samples were inserted into each block of 20 stream sediment (silt) samples.

### **3.2 Stream Water Samples**

One set of water samples was filtered within 24 hours of collection through single-use Millipore Sterivex-HV 0.45-µm filter units attached to 50-ml or 60-ml sterile plastic syringes (syringes were re-used after rinsing with distilled, deionized water, but replaced daily). After 50 ml of water was filtered into new 60-ml bottles, the remainder was used for the determination of pH and conductivity before being discarded. Using an Eppendorf pipettor with disposable plastic tips, 0.5 ml of 16M nitric acid ( $\text{HNO}_3$ ) was added to filtered water samples. At this point, control reference samples (filter, acid and travel blanks) were inserted. Filtered and acidified waters were kept in a cool, dark place until shipment to the lab. Control reference samples were inserted into each block of 20 water samples. No duplicate water samples were collected.

The second set of water samples was shipped to the laboratory for analysis without modification (analytical results from these unmodified samples are not included in this report).

## **4 Analytical Procedures**

### **4.1 Stream Sediment Determinations by Inductively Coupled Plasma Mass Spectrometry**

Determinations of nickel, copper, zinc, arsenic, molybdenum, silver, barium, mercury and lead (and additional elements not released in this report) in the <80 mesh fraction of the stream silt samples by inductively coupled plasma mass spectrometry (ICP-MS) was completed by Acme Analytical Laboratories of Vancouver, British Columbia. For each sample, one gram of <80 mesh material was leached with 6 ml of HCl,  $\text{HNO}_3$ , and distilled, deionized water, in equal volume proportions, at 95° C for one hour. The sample solution was diluted with deionized water to 20 ml and analysed by inductively coupled plasma emission spectroscopy on a Jarell-Ash instrument and inductively coupled plasma mass spectroscopy on a Perkin-Elmer Elan instrument. Lower detection limits by ICP-MS are listed in Table 1.

Table 1. ICP-MS lower detection limits (stream sediment samples).

| Element         | Lower Detection Limit |
|-----------------|-----------------------|
| Nickel (Ni)     | 0.1 ppm               |
| Copper (Cu)     | 0.01 ppm              |
| Zinc (Zn)       | 0.1 ppm               |
| Arsenic (As)    | 0.1 ppm               |
| Molybdenum (Mo) | 0.01 ppm              |
| Silver (Ag)     | 2 ppb                 |
| Barium (Ba)     | 0.5 ppm               |
| Mercury (Hg)    | 5 ppb                 |
| Lead (Pb)       | 0.01 ppm              |

#### 4.2 Water pH and Conductivity

The pH of stream waters was determined using a Hanna Instruments HI 98129 pH and EC meter with automatic temperature compensation, a pH range of 0.00 to 16.0, resolution of 0.01 pH and a stated accuracy of  $\pm 0.01$  pH at  $20^\circ \text{C}$ . The meter was calibrated during the survey using commercial buffer solutions.

The conductivity of stream waters was determined using a Hanna Instruments HI 98129 pH and EC meter with automatic temperature compensation, a conductivity range of 0 to 3999  $\mu\text{S}/\text{cm}$ , a resolution of 1 microsiemen ( $\mu\text{S}/\text{cm}$ ) and a stated full-scale accuracy of  $\pm 2\%$ , and a temperature compensation coefficient ( $\beta$ ) of 1.9 (factory setting). The meter was calibrated during the survey using commercial conductivity standards.

### 5 Results

Maps showing selected geochemical results from the 2001 to 2004 NGR stream water and stream sediment (<80 mesh) surveys in the Buffalo Head Hills area are presented in Appendix 2. Stream water pH and conductivity measurements from the 2004 water samples are listed in Appendix 3 and ICP-MS values from the 2004 stream sediment (<80 mesh) samples are listed in Appendix 4.

### 6 Discussion

Markedly acidic waters occur in some streams draining the northern Buffalo Head Hills (pH values as low as 3.3). In addition, streams draining the northern and northeastern flanks of the Buffalo Head Hills are commonly characterized by relatively elevated conductivity values. In comparison to stream sediments from other parts of the Buffalo Head Hills area, the stream sediments (silts) collected from streams flanking the northern Buffalo Head Hills tend to contain elevated amounts of nickel, copper, zinc, molybdenum, silver, mercury, lead and, to a lesser extent, barium.
