Introduction

Coal, believed to be suitable as feedstock for on-site conversion plants, is found in many very large deposits in the Alberta Plains; some of these deposits are difficult of access, others are already dedicated to thermoelectric power production, but many remain uncommitted. The Alberta Research Council presents the following report — an update and expansion of previous issues — as a guide to those coal deposits that are both suitable and available for conversion process.

It is believed that, under conditions foreseeable for the near future in Alberta,

- 1. the preferred feedstock for on-site coal conversion process should be subbituminous coal;
- liquefaction (total transformation of coal to liquid hydrocarbon) and pyrolysis (stripping small amounts of valuable fluid hydrocarbon from coal, leaving a solid char residue available for combustion) will be the dominant conversion processes;
- economic *liquefaction* process units would each produce more than 50,000 bbl/day for 30 years and would require dedicated coal reserves of about 250 x 10⁶ tonnes (about 300 x 10⁶ short tons);
- pyrolysis processes will be mated to major thermoelectric power plants that are sited on dedicated coal reserves of 120 x 10° tonnes (about 140 x 10° short tons) or more.

Accordingly, the Alberta Research Council and Alberta Energy and Natural Resources direct the attention of interested parties to 15 "Coal Regions" in the Alberta Plains shown on the map (figure 1), summarized in table 1 and described in detail in the Appendix. All 15 of these "Regions" are easily accessible, possess already-developed social infrastructure and contain adequate reserves of subbituminous coal recoverable

by current mining technology to support one or more process plants. None of them present insurmountable problems of use-conflict with agriculture, recreation or ecologically fragile environments.

Of the 15 "Coal Regions" thus delineated, 9 are believed to be suited to the liquefaction process industry; they contain adequate reserves and are not dedicated at present to power generation. These regions are numbers 1 through 9 in table 1. The remaining 6 "Regions," while not specifically excluded from liquefaction, are probably more suitable for power generation and in some cases are already dedicated to that use; these 6 are worth considering as sites for mated power/pyrolysis industry. These regions are numbered 10 through 15 in table 1.

The 15 "Regions" chosen for this report, while not coterminous with the administrative "Fields" of the Alberta Energy Resources Conservation Board (ERCB, 1982), are designated by reference to ERCB field names and consist of component sub-regions or "Deposits" that are identical to the "Deposits" of the ERCB. For instance, the Region "Mayerthorpe/Wabamun (part)" consists of 3 "Deposits" of the ERCB "Mayerthorpe" Field and 2 "Deposits" of the ERCB "Wabamun" Field.

Each "Deposit" referred to in this report has been assigned an arbitrary consecutive number, from 1 to 57, identified in the Appendix. These numbers are used for reference in the location map (figure 1), and in table 2.

The reserve tonnages reported below for each Region are those quoted by the Alberta Energy Resources Conservation Board for the respective "Deposits" (see ERCB, 1982).

Coal properties

Coal rank (ASTM) in the Alberta Plains ranges from high volatile C bituminous to Lignite A. Highest rank coals occur along the southwestern boundary of the Plains nearest the Rocky Mountain Foothills; decreasing ranks of coal are met at increasing distances eastward and northeastward. None of the Plains coals show caking properties.

All of the coal deposits noted in the Appendix (except the largely unsubstantiated Buffalo Hill Region) happen to be subbituminous B or subbituminous C in rank; these are the Plains coal deposits that are now economically accessible. Considerable tonnages of subbituminous A coals, however, lie in physically or economically inaccessible areas near the Rocky

Mountain Foothills, especially in northwestern Alberta. To facilitate small-scale study, the Alberta Research Council has collected one bulk sample representative of such coals from a collecting locality ("Smoky Tower") in Tp 63, R 2, W 6th Mer (54°26′N; 118°16′W), indicated in figure 1.

The analytical determinations reported in the Appendix for each Region were made in laboratories of the Alberta Research Council; proximate and elemental analyses are given, together with specific gravity and ash-fusion determinations when available. (See also Stansfield and Lang, 1944.)

Geologically, all "Deposits" referred to in this report are part of a single enormous wedge of coal-measures (with a few relatively thin marine bands included) that blankets the central and southern parts of Alberta. Although the "Deposits" occur at three distinct horizons within the wedge, they are so closely spaced in age (latest Cretaceous to earliest Paleocene) that they may be considered almost synchronous. The three horizons are: Oldman Formation (Early Late Cretaceous age); Horseshoe Canyon Formation (Late Cretaceous age); Scollard Member of Paskapoo For-

mation (Latest Cretaceous or Cretaceous-Paleocene boundary age).

Two major experimental and scale-up programs are under way to test Plains coals for their behavior in liquefaction and pyrolysis processes, but results are not yet suitable for publication.

In the last few years, substantial attention has been paid to the petrography of Alberta Plains coals in the laboratories of both the Institute of Sedimentary and Petroleum Geology, Calgary, and the Alberta Research Council, Edmonton. Considerable progress has already been made towards correlating petrographic analysis with performance of the coals in conversion processes (Parkash et al., 1982). Table 2 presents petrographic analyses from Parkash et al. of 10 Alberta Plains coal samples that will serve for the present to demonstrate the range of petrographic variability. It should be noted that, in keeping with their immature rank, these coals contain considerable amounts of imperfectly formed vitrinite retaining much of the original woody (coniferous: Taxodiaceous) structure.

Appendix

Coal regions for conversion, Alberta Plains

First region: Fox Creek (part)

Rank (ASTM):

Subbituminous B

Geology:

Scollard Member Paskapoo Formation; latest Cretaceous age

Location:

240 km NW of Edmonton, about Tp 65, R 19, W 5 Mer

Deposits	Number		ning Reserves nnes x 10 ^e	Note
	(figure 1)	Strip	Underground	
Giroux	1	110	0	Estimates, especially under-
Atikkamek	2	100	0	ground, believed to be much too
Meekwap W	3	130	0	conservative; numerous dirt
Meekwap E	4	160	23	partings
S. Brush Mtn.	5	210	24	, 5
Goose River	6	45	0	
Total		755	47	

Mineability: Seams thick; ash content variable; stripping ratios favorable; topography flat to rolling; conventional oil and gas fields can be integrated with mining.

Environmental constraints: low

No agriculture; critical wildlife area limited and clearly segregated; much muskeg; harvesting of productive forest can be integrated with mining.

Socioeconomic constraints: low

Rail line; main highway; local oilfield road network; town of Fox Creek (pop. 2000), an oilfield resupply point; recreation areas clearly segregated.

Typical analyses (Attikamek Deposit)

Proximate (capacity moisture, mineral-matter-free basis)

Capacity moisture

% - 20.3

Ash (as received)

% - (11.5)

Fixed carbon

% - 48.9

Calorific value

Btu/lb -10.440

Ultimate (elemental; water out)

Sulfur

% - 0.6

Significantly comparable coal, available as bulk samples: Highvale Mine, Wabamun Coal Region, Tp 52, R 4, W 5 Mer (53°29'N; 114°34'W).

Second Region: South Swan Hills

Rank (ASTM):

Subbituminous C

Geology:

Scollard Member Paskapoo Formation latest Cretaceous age

Location:

160 km W of Edmonton, about Tp 64, R 10, W 5 Mer

Deposits	Number (figure 1)		ining Reserve nnes x 10 ⁶ Underground	Note
Freeman Creek	7	10	0	Estimates, especially under-
Judy Creek	8	230	76	ground, believed to be much too
Carson Lake	9	55	19	conservative; much very dirty
Total		295	95	coal.

Mineability:

Seams thick; ash content variable; stripping ratios favorable in places; topography rolling; conventional oil and gas fields can be integrated with mining.

Environmental constraints: low to medium

No agriculture; critical wildlife area partly segregated; harvesting of productive forest can be integrated with mining.

Socioeconomic constraints: low to medium

No rail line; secondary highway; local oilfield road network; town of Swan Hills (pop. 1500), an oilfield resupply point; recreation areas clearly segregated.

Typical analyses (Freeman Creek Deposit)

Proximate (capacity moisture, mineral-matter-free basis)

Capacity moisture

% - 25.3

Ash (as received)

% - (16.6)

Fixed carbon

% - 40.9

Calorific value

Btu/lb - 8,690

Third region: Mayerthorpe/Wabamun (part)

Rank (ASTM):

Subbituminous B

Geology:

Scollard Member Paskapoo Formation, latest Cretaceous age

Location:

75 km W of Edmonton, about Tp 54, R 7, W 5 Mer

Deposits	Remaining Reserves Number Tonnes x 10 ⁸			Note
	(figure 1)	Strip	Underground	
Rochfort Bridge	10	3	12	Estimates, especially under-
Jalna	11	31	300	ground, believed to be much too
Evansburg	12	0	280	conservative.
Stanger	13	27	0	
Magnolia	14	94	10	
Total		155	602	

Mineability:

Seams medium to thick; ash content variable; stripping ratios favorable in places; topography flat.

Environmental constraints: low

Little agriculture; critical wildlife areas limited and clearly segregated; much muskeg; little productive forest.

Socioeconomic constraints: low

Main rail line; main highways; some local roads; established villages (Mayerthorpe, Evansburg, Entwistle, Wildwood); recreation areas limited and clearly segregated.

Typical analyses (Magnolia Deposit)

Proximate (Capacity moisture, mineral-matter-free basis)

Capacity moisture % - 21.8
Ash (as received) % - (10.3)
Fixed carbon % - 49.3
Calorific value Btu/lb - 10,230

Horseshoe Canyon Formation, late Cretaceous age

Location:

165 km ENE of Calgary, about Tp 29, R 13, W 4 Mer

Remaining Reserve

Deposits

Number

50

Tonnes x 106

Note

(figure 1)

Strip Underground

Sheerness

140

0

Major strip mine and minemouth thermoelectric power plant under construction; no

underground extension.

Mineability:

Seams thick; ash content low; stripping ratio very favorable; topography flat.

Environmental constraints: low to medium

Poor to fair agricultural land; severe water deficit.

Socioeconomic constraints: low

Rail lines; highways; good local road network; established towns and villages (Hanna, Sheerness).

Typical analyses

Proximate (capacity moisture, mineral-matter-free basis)

Capacity moisture

% - 29.4

Ash (as received)

% - (5.9)

Fixed carbon

Hydrogen

% - 4.8

Nitrogen

% - 1.4

Oxygen

% - 19.8

Sulfur

% - 0.6

Representative coal, available as bulk samples: Sheerness Mine, Tp 29, R 13, W 4 Mer (51°28'N; 111°42'W).

Twelfth Region: Drumheller (part)

Rank (ASTM): Geology:

Subbituminous B (some Subbituminous A) Horseshoe Canyon Fm., late Cretaceous age

Location:

105 km NE of Calgary, about Tp 28, R 19, W 4 Mer

Deposits	Number	Tonnes x 10°		Note
	(figure 1)	Strip	Underground	
Munson,				
Kneehill	51	0	280	Underground estimates believed
Rosedale,				to be too conservation by one
Eladesor	52	3	138	order of magnitude.
East Coulee,				
Western				
Monarch	53	0_	43	
Total		3	461	

Mineability:

Seams thick, nearly flat-lying; ash content low; no strippable deposits; deep coulees allow level entry; roof conditions favorable.

Environmental constraints: low

Cover (300-500 feet) need not be disturbed.

Socioeconomic constraints: low

Main rail line; highways; good local road network; established mining city (Drumheller); recreation areas can be clearly segregated.

Typical analyses (Rosedale Deposit)

Proximate (capacity moisture, mineral-matter-free basis)

Capacity moisture

% - 21.6

Ash (as received)

% - (5.0)

100

Underground Strip

Note

Blackfoot

54

22

Underground estimates believed

to be conservative; seams continuous westward to Buffalo Hill

Region.

Mineability:

Seams thick; ash content moderate; stripping ratio favorable within bounds of Bow River Valley: topography in valley rolling.

Environmental constraints: medium

Good agricultural land.

Socioeconomic constraints: low

Main rail line; main highway; some local roads; established towns (Bassano, Cluny, Gleichen); Indian lands.

Typical analyses

Proximate (capacity moisture, mineral-matter-free basis)

Capacity moisture

% - 20.0

Ash (as received)

% - (10.5)

Fixed carbon

% - 47.4

Calorific value

Fourteenth Region: Buffalo Hills

Rank (ASTM):

Subbituminous A (probably)

Geology:

Horseshoe Canynon Formation, late Cretaceous age

Location:

85 km SE of Calgary, about Tp 18, R 23, W 4 Mer

Deposits	Number	Remaining Reserve Tonnes x 10°		Note
	(figure 1)	Strip	Underground 440	
Buffalo Hill	55	0	440	New Region, entirely very deep underground; enormous reserves and high rank reported, but yet to be substantiated.

Mineability:

Entirely underground with vertical hoisting shafts required; deeper (more than 400 m) than any mine ever in Alberta Plains.

Environmental constraints: low Cover need not be disturbed.

Socioeconomic constraints: low

Rail line; highway; good local road network; established town (Vulcan).

(Analyses confidential; not available; coal reported to be Subbituminous A in rank.)

Fifteenth Region: Brooks/East Brooks (part)

Rank (ASTM):

Subbituminous B

Geology:

Oldman Formation, late Cretaceous age

Location:

250 km SE of Calgary, about Tp 17, R 15, W 4 Mer

Deposits	Number (figure 1)	Remaining Reserve Tonnes x 10° Strip Underground		Note	
Bow City - Kitsim	56	67	38	Two 'Fields' (ERCB) necessary	
East Brooks Total	57	76 140	0 40	for one viable operation.	

Mineability:

Medium-thin seams; medium-large stripping ratios; topography flat.

Environmental constraints: medium

Some irrigation agriculture; some critical wildlife areas (antelope).

Socioeconomic constraints: low

Main rail line; main highway; good local road network; established town (Brooks).

Typical analyses (Bow City - Kitsim Deposit)

Proximate (capacity moisture, mineral-matter-free basis)
