F	Fen peat: Occurs in a peatland with water take dominated by sedges, with grasses and reeds COLLUVIAL DEPOSITS: Materials that have movement; commonly occurs as slope and sl		
F	movement; commonly occurs as slope and sl	surface is dominated by sphagnum mosses, heath shrubs and short, stunted trees. Fen peat: Occurs in a peatland with water table at surface and slow internal drainage; peatland surface is dominated by sedges, with grasses and reeds near local pools, and is sparsely treed.	
		COLLUVIAL DEPOSITS: Materials that have reached their present position as a result of direct, gravity-indumovement; commonly occurs as slope and slump deposits confined to valley slopes and floors; includes pre-existing bedrock, till, glaciolacustrine, glaciofluvial and eolian sediments, generally poorly sorted.	
	FLUVIAL DEPOSITS: Sediments transported and deposited by streams and rivers; synonymous with alluvial Includes well-sorted stratified sand, gravel, silt, clay and organic sediments occurring in channel and overbandeposits (e.g., postglacial floodplains, terraces, fans and deltas).		
L	LACUSTRINE DEPOSITS: Sediments deposited in and adjacent to recent and modern lakes; offshore sand silt and clay, minor organic deposits; may include minor littoral (nearshore) beaches and bars; sand, silt and minor gravel.		
E	EOLIAN DEPOSITS: Wind-deposited sediments; well-sorted, medium to fine-grained sand and minor silt (loess); generally massive to locally cross bedded or ripple laminated; includes both active and vegetated deposits.		
PLEISTOCENI	E.		
LG	GLACIOLACUSTRINE DEPOSITS: Primarily fine-grained, distal sediments deposited in or along the margin of glacial lakes, including sediments released by the melting of floating ice. Includes laminated (rhythmically bedded) to massive fine sand, silt and clay, and may contain ice-rafted stones.		
LGL		to stratified, well-sorted silty sand, pebbly sand and minor graesets deposited during regression and lowering of glacial	
FG	GLACIOFLUVIAL DEPOSITS: Sediments deposited by glacial meltwater streams as subaerial or subaqueou outwash. Includes sand and gravel, often stratified, minor silt, and may show evidence of ice melting (slumpe structures). Features include meltwater channels, kettle holes, terraces and minor ice-contact sediments.		
FGI	either in front of (kame terraces) or within (es	d by glacial meltwater streams in direct contact with glacial ice kers, crevasse ridges) glacial ice. Includes massive to stratified (predominantly pebble gravel and coarse sand, locally till) and tructures).	
M		ed directly by glacial ice consisting of a mixture of clay, silt, sa cally, this unit may contain blocks of bedrock, pre-existing olacustrine and/or glaciofluvial sediment.	
MS	Stagnant ice moraine: Material resulting from the collapse and lateral movement of englacial and supraglac sediment in response to melting (ablation) of buried stagnant ice at the ice margin; sediment is mainly diamic but locally includes stratified sediments of glaciolacustrine or glaciofluvial origin. Characterized by low to high relief hummocky topography.		
МТ	by the glacier more or less intact; deposits ma	acio-tectonic transport of originally subglacial material deposite by include syngenetic till, as well as masses of pre-existing till, by high to moderate relief and features include hill-hole pairs a	
MF	Fluted moraine: Glacially streamlined terrain	; varies from alternating furrows and ridges to nearly equidime ice flow direction; includes flutes, drumlins and drumlinoids.	
FP	PREGLACIAL FLUVIAL DEPOSITS: Sediments transported and deposited by streams and rivers prior to glaciation. This includes sand and gravel deposits occurring in paleovalleys (i.e., preglacial floodplains, terra fans and deltas) ranging from late Tertiary to middle Wisconsin.		
PRE-QUATERNARY		middle viloconom.	
RT	UNCONSOLIDATED FLUVIAL GRAVELS:	Predominately well-sorted, quartzite and chert gravel and cobb	
KI	Cordilleran source, Paleogene (Tertiary) to ea	arly Quaternary.	
R	BEDROCK: Undivided; may include crystalling	ne (Shield), carbonate or clastic sedimentary rock and/or coal.

UNIT NOTATION

Example: sandy GLACIOLACUSTRINE plain

Textural Modifier

Textural characteristics may be applied to the terrain classification as a prefix based on field observations or by inference from distinctive genesis and/or morphology. When two modifiers are given, the second letter is the

dominant texture, with the first letter indicating the secondary texture; i.e., sc for sandy clay.

p = pebble g = gravel

s = sand = silt

c = clay a = sand-silt-clay

GENETIC & GEOMORPHIC MODIFIERS

c crevasse fill ice-contact ridges, ice-squeeze deposits and linear forms deposited by meltwater in stagnant ice

d doughnut rings circular hummocks with a central depression, plateau mounds and brain-like pattern ridges, low to moderate relief

planar surface eroded by glacial meltwater, often capped by a boulder lag deposit and/or thin deposit of sand and gravel gently sloping fan-shaped mass of detrital debris

slopes dissected by modern ravines created by intermittent runoff assemblage of approximately equidimensional hills and hollows; moderate to high relief (commonly greater than 2 m)

depression, including kettles, pitted morphology, thermokarst depressions, karst sinkholes sinuous curves, loops and oxbows produced as meltwater and modern streams shift their channels over time

deposit greater than 2 m thick; commonly masks geomorphic pattern of underlying deposits; flat to gently rolling topography one or more parallel or subparallel, convex, linear morphological elements with a length-to-width ratio greater than 2;

low to high relief landslide blocks, slope failure debris

terrace bench cut by either meltwater or wave action; antiplanation terrace, kame terrace low-relief rolling terrain; swell and swale topography

thin mantle of unconsolidated material too thin to mask the minor irregularities of the surface of the underlying material; it ranges in thickness from 10 cm to 1 metre and may be discontinuous. In places material, particularly the lacustrine sediment, may be 2 m or more thick

low-relief transverse moraine ridges, usually formed from basal ice shearing channelled or dissected by glacial meltwater flow; dissected terrain by Holocene fluvial activity

lake delta; ice-contact delta

Where two or more classes of terrain are interspersed in a mosaic or repeating pattern on a scale too small to warrant meaningful differentiation, the proportion of each component in the combination is given in a two or three-position designation set off by slashes denoting arbitrary percentage limits. For example,

'Mp/LGv' means the area is underlain by approximately 60% morainal plain and up to 40% glaciolacustrine veneer.

'Mv/LGv/FGp' means at least 60% of the area is underlain by morainal veneer, with up to 40% glaciolacustrine veneer and less than 15% glaciofluvial plain. 'LGp//M' means more than 60% of the area is underlain by a glaciolacustrine plain, with less than 15% moraine.

Stratigraphic Sequence

Where materials of different origins or textures are known to be superimposed or can be confidently inferred, the sequence is indicated in conventional order using vertical separators, such as:

'sLGv | Mp' Thin sandy glaciolacustrine sediment deposited on morainal plain

Transitional Association

Locally, two or more terrain units are juxtaposed by reason of related origin, temporal sequence or ambiguous geomorphic distinction. In the last case, both components may or may not be present. Such situations are identified by a compound designation marked by a hyphen. Examples are:

'FGz-LGz' indicating ice-contact delta indistinguishable from glaciolacustrine delta, or

indicating glaciolacustrine indistinguishable from littoral and nearshore glaciolacustrine sediment

Morphologic Overprint

Where a sequence of geomorphic processes has produced a multi-aspect or compound terrain fabric, the geomorphic modifier suffixes are appended in the inferred order of superposition. 'Mpry' means a plain of till has been moulded into ridge forms and finally dissected by modern streams. 'FGphr' means a glaciofluvial plain has been discontinuously covered by ice-contact hummocks and ridges.

Acknowledgements

Surficial mapping was completed in 2008 as an Alberta Geological Survey (AGS) contribution to the Quaternary mapping initiative under the Alberta Mineral Strategy. N. Oviatt and C. Parker assisted with fieldwork. Digital cartography and GIS were completed by K. Mckay and GISmo Solutions Ltd. Base data were provided by Spatial Data Warehouse Ltd. M. M. Fenton (AGS) provided constructive comments that improve this map.
